Abstract Recent physiological findings revealed that about one-third of motion-sensitive neurons in the primate pretectal nucleus encoded the acceleration of visual motion. Here we propose a mechanistic hypothesis, in which the slow adaptive depression plays a significant role in response generation to acceleration for the cortex of the three important populations of the acceleration-sensitive neurons: the phosphenic-shaped speed-tuning curves, the opposed-signed after-responses (OSARs) and the acceleration sensitivities. The flat plateau within the speed-tuning curves and the OSARs to motion offset observed in experiments are reproduced successfully as simulations, and the similar responses of the acceleration-sensitive neurons to step changes, step changes in step size, speed and step size modulation, a stimulus speed discontinuity consistent with physiological observations. Thus, a biologically plausible account for the response characteristics and the origin of the three properties are provided.

1 Introduction

Stabilizing images on the retina is very important for animal individuals to keep a clear vision. In vertebrate, both the vestibular system and the optokinetic system are involved in the generation of the compensatory eye movement caused by self-motion.

In both, the vestibular system consists of two nuclei, the nucleus loquax (nucleus reticularis) (LM) in primate and the nucleus of the horizontal optokinetic system (NHS) of the macaque optic system (Ogawa 1984; McKenna and Wallman 1987). They are thought to be homologous to the pretectal nucleus of the optic tract (NPO) and the central nucleus of the superior colic, tract in mammals (Kallmeyer 1979; McKenna and Wallman 1987).

Although a number of spatial and temporal similarities between the responses of vestibular neurons to self-motion and the responses of neurons in the optokinetic

system to visual motion were reported (Miles 1961; Wiley et al. 1964; Frazier 1968; Wiley and Cowder 2001; Robinson and Price 2011), whether visual neurons involved in optokinetic eye-egress would also respond to accelerations remained unknown for many years.

Recently, an experimental finding (Guo et al. 2004) in pigeons in LM revealed that about one-third of motion-sensitive neurons in the macular nucleus exhibit a response to wide-field visual motion. The acceleration-sensitive neurons show some novel response properties, such as the phosphenic-shaped speed-tuning curves in the preferred direction and a transient inhibition in the firing rates elicited by a sudden step of visual motion in the preferred direction and a transient excitation evoked by a sudden step of visual motion in the null direction. The transient step after-response were observed in a controlled fact with the electrophysiological stimuli (Robinson and Miles 1994; Wiley and Cowder 2000; Cowder and Wiley 2011) and were referred to as opposed-sign after-responses, or short OSARs (Prazak and Robinson 2012). And it is interesting to note that there exist a significant correspondence between the shape of the speed-tuning curves and the presence of the after-responses to motion offset. The similarity was also thought to be diagnostic for the presence or absence of responses related to target acceleration or deceleration.

In this paper we propose a computational model to simulate the acceleration-sensitive neurons in pigeon optokinetic system. Based on the hypothesis that the slow adaptive depression plays a significant role in shaping responses of the macular nucleus neurons to visual motion, a plausible explanation for the possible origin of the OSARs, the phosphenic-shaped speed-tuning curves and the acceleration sensitivities is presented.

Abstract Recent physiological findings revealed that about one-third of motion-sensitive neurons in the primate pretectal nucleus encoded the acceleration of visual motion. Here we propose a mechanistic hypothesis, in which the slow adaptive depression plays a significant role in response generation to acceleration for the origin of the three important properties of the acceleration-sensitive neurons: the plateau-shaped speed-tuning curves, the opposed-sign after-responses (OSARs) and the acceleration sensitivities. The flat plateau within the speed-tuning curves and the OSARs to motion reflect observed in experiments are reproduced successfully as simulations, and this similar response of the acceleration sensitive neurons to step changes, step changes in step size, speed and step size modulation, a stimulus speed discontinuity consistent with physiological observations. This is biologically plausible account for the response characteristics and the origin of the three properties are provided.

1 Introduction

Stabilizing images on the retina is very important for animal individuals to keep a clear vision. In vertebrate, both the vestibular system and the optokinetic system are involved in the generation of the compensatory eye movement caused by self-motion.

In both, the vestibular system consists of two nuclei, the nucleus loquax and nucleus prepositus (LM) in mammalian and the nucleus of the horizontal eye (NHE) of the tectal optic system (Olivace 1984; McKenna and Wallman 1987). They are thought to be homologous to the pretectal nucleus of the optic tract (NPT) and the central nucleus of the tectal optic tract in mammals (Kallnick 1979; McKenna and Wallman 1987).

Although a number of spatial and temporal similarities between the responses of vestibular neurons to self-motion and the responses of neurons in the optokinetic system to visual motion were reported (Miles 1981; Wiley et al. 1984; Frazee 1998; Wu and Cowder 2001; Robinson and Price 2011), whether visual neurons involved in optokinetic responses would also respond to accelerations remained unknown for many years.

Recently, an experimental finding (Guo et al. 2004) in pigeons in LM revealed that about one-third of motion-sensitive neurons in the nucleus loquax exhibit a response to acceleration of wide-field visual motion. The acceleration-sensitive responses show some novel responses properties, such as the plateau-shaped speed-tuning curves in the preferred direction and null direction, a transient inhibition during step changes in step size, and a transient excitation during a null step change in step size.

The acceleration-sensitive responses were observed in a controlled fact with the step changes in step size (Robinson and Miles 1996; Wu and Cowder 2000; Cowder and Wiley 2011) and were related to optokinetic eye movements, for which OSARs (Prazee and Robinson 2012). And it is interesting to note that there exist a significant correspondence between the shape of the speed-tuning curves and the presence of the after-response to target acceleration or deceleration.

It has been thought to be diagnostic for the presence or absence of compensatory eye movements to target acceleration or deceleration.

In this paper we propose a mechanistic model to simulate the acceleration-sensitive neurons in primate optokinetic system. Based on the hypothesis that the slow adaptive depression plays a significant role in shaping responses of the acceleration-sensitive neurons to visual motion, a plausible explanation for the possible origin of the OSARs, the plateau-shaped speed-tuning curves and the acceleration sensitivities is presented.

2 Model the acceleration-sensitive neurons in pigeon optokinetic system

2.1 Neuronal microcircuitry hypothesis

A number of physiological observations (see for example, Cowder and Cowder 1998) and computational simulations (see for example, Lohr et al. 2007) have demonstrated

that the acceleration-sensitive neurons in primate optokinetic system are involved in the generation of the compensatory eye movement caused by self-motion. In both, the vestibular system consists of two nuclei, the nucleus loquax and nucleus prepositus (LM) in mammalian and the nucleus of the horizontal eye (NHE) of the tectal optic system (Olivace 1984; McKenna and Wallman 1987). They are thought to be homologous to the pretectal nucleus of the optic tract (NPT) and the central nucleus of the tectal optic tract in mammals (Kallnick 1979; McKenna and Wallman 1987).

Although a number of spatial and temporal similarities between the responses of vestibular neurons to self-motion and the responses of neurons in the optokinetic system to visual motion were reported (Miles 1981; Wiley et al. 1984; Frazee 1998; Wu and Cowder 2001; Robinson and Price 2011), whether visual neurons involved in optokinetic responses would also respond to accelerations remained unknown for many years.

Recently, an experimental finding (Guo et al. 2004) in pigeons in LM revealed that about one-third of motion-sensitive neurons in the nucleus loquax exhibit a response to acceleration of wide-field visual motion. The acceleration-sensitive responses show some novel responses properties, such as the plateau-shaped speed-tuning curves in the preferred direction and null direction, a transient inhibition during step changes in step size, and a transient excitation during a null step change in step size.

The acceleration-sensitive responses were observed in a controlled fact with the step changes in step size (Robinson and Miles 1996; Wu and Cowder 2000; Cowder and Wiley 2011) and were related to optokinetic eye movements, for which OSARs (Prazee and Robinson 2012). And it is interesting to note that there exist a significant correspondence between the shape of the speed-tuning curves and the presence of the after-response to target acceleration or deceleration.

In this paper we propose a mechanistic model to simulate the acceleration-sensitive neurons in primate optokinetic system. Based on the hypothesis that the slow adaptive depression plays a significant role in shaping responses of the acceleration-sensitive neurons to visual motion, a plausible explanation for the possible origin of the OSARs, the plateau-shaped speed-tuning curves and the acceleration sensitivities is presented.

2 Model the acceleration-sensitive neurons in pigeon optokinetic system

2.1 Neuronal microcircuitry hypothesis

A number of physiological observations (see for example, Cowder and Cowder 1998) and computational simulations (see for example, Lohr et al. 2007) have demonstrated

that the acceleration-sensitive neurons in primate optokinetic system are involved in the generation of the compensatory eye movement caused by self-motion. In both, the vestibular system consists of two nuclei, the nucleus loquax and nucleus prepositus (LM) in mammalian and the nucleus of the horizontal eye (NHE) of the tectal optic system (Olivace 1984; McKenna and Wallman 1987).

Although a number of spatial and temporal similarities between the responses of vestibular neurons to self-motion and the responses of neurons in the optokinetic system to visual motion were reported (Miles 1981; Wiley et al. 1984; Frazee 1998; Wu and Cowder 2001; Robinson and Price 2011), whether visual neurons involved in optokinetic responses would also respond to accelerations remained unknown for many years.

Recently, an experimental finding (Guo et al. 2004) in pigeons in LM revealed that about one-third of motion-sensitive neurons in the nucleus loquax exhibit a response to acceleration of wide-field visual motion. The acceleration-sensitive responses show some novel responses properties, such as the plateau-shaped speed-tuning curves in the preferred direction and null direction, a transient inhibition during step changes in step size, and a transient excitation during a null step change in step size.

The acceleration-sensitive responses were observed in a controlled fact with the step changes in step size (Robinson and Miles 1996; Wu and Cowder 2000; Cowder and Wiley 2011) and were related to optokinetic eye movements, for which OSARs (Prazee and Robinson 2012). And it is interesting to note that there exist a significant correspondence between the shape of the speed-tuning curves and the presence of the after-response to target acceleration or deceleration.

In this paper we propose a mechanistic model to simulate the acceleration-sensitive neurons in primate optokinetic system. Based on the hypothesis that the slow adaptive depression plays a significant role in shaping responses of the acceleration-sensitive neurons to visual motion, a plausible explanation for the possible origin of the OSARs, the plateau-shaped speed-tuning curves and the acceleration sensitivities is presented.

Abstract. Recent physiological findings revealed that about one-third of motion-sensitive neurons in the primate pretectal nucleus encoded the acceleration of visual motion. Here we propose a mechanistic hypothesis, in which the slow adaptive depression plays a significant role in response generation to acceleration for the majority of the three important populations of the acceleration-sensitive neurons: the plateau-shaped speed-tuning curves, the opposed-signed after-responses (OSARs) and the acceleration sensitivities. The flat plateau within the speed-tuning curves and the OSARs to motion offset observed in experiments are reproduced successfully as simulations, and the similar responses of the acceleration sensitive neurons to step changes, step changes in step speed and step speed modulation of stimulus speed are qualitatively consistent with physiological observations. This is biologically plausible simulation for the response characteristics and the origin of the three properties are provided.

1 Introduction

Stabilizing images on the retina is very important for animal individuals to keep a clear vision. In vertebrate, both the vestibular system and the optokinetic system are involved in the generation of the compensatory eye movement caused by self-motion (for review, see Robinson 1995). In birds, the optokinetic system consists of two nuclei, the nucleus tectalis nucleus (NTN) in pretectum and the nucleus tectalis nucleus (NTN) in pretectum and the nucleus tectalis nucleus (NTN) in pretectum (for review, see Robinson 1995). The two nuclei were thought to be homologous to the pretectal nucleus of the optic tract (PNOT) and the central nucleus of the superior colliculus in mammals (Kallnick 1979; McKenna and Wallman 1981). Although a number of spatial and temporal similarities between the responses of vestibular neurons to self-motion and the responses of neurons in the optokinetic system to visual motion were reported (Miles 1984; Wiley et al. 1984; Frazee 1993; Wu and Cowder 2001; Robinson and Price 2001), whether visual neurons involved in optokinetic eye-egress would also respond to accelerations remained unknown for many years.

Recently, an experimental finding (Guo et al. 2004) in pigeons in LM revealed that about one-third of motion-sensitive neurons in the nucleus tectalis nucleus (NTN) in pigeons showed some novel response properties, such as the plateau-shaped speed-tuning curves in the preferred direction and null direction, an unusual inhibition during step changes in step speed and a transient inhibition during a modulation of step speed in the null direction. The unusual step responses were observed in a simulated flat cells in the optokinetic system (Robinson and Miles 1994; Wiley and Cowder 2000; Cowder and Wiley 2001) and were related to an eye-egress after-response, so-called OSARs (Prazee and Robinson 2002). And it is interesting to note that there exist a significant correspondence between the shape of the speed-tuning curves and the presence of the after-response to motion offset. The similarity may also be thought to be diagnostic for the presence or absence of responses related to target acceleration or deceleration.

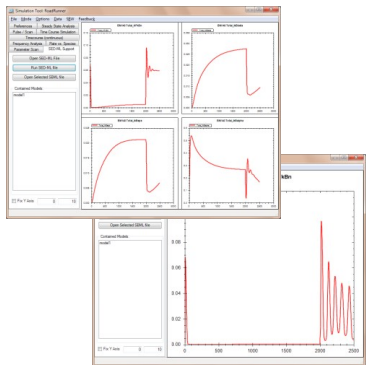

In this paper we propose a mechanistic model to simulate the acceleration sensitive neurons in pigeon optokinetic system. Based on the hypothesis that the slow adaptive depression plays a significant role in shaping responses of the acceleration sensitive neurons to visual motion, a plausible explanation for the possible origin of the OSARs, the plateau-shaped speed-tuning curves and the acceleration sensitivities is presented.

Abstract Recent physiological findings revealed that about one-third of motion-sensitive neurons in the primate pretectal nucleus encoded the acceleration of visual motion. Here we propose a mechanistic hypothesis, in which the slow adaptive depression plays a significant role in response generation to account for the curves of the three important properties of the acceleration-sensitive neurons: the phasically-shaped speed-tuning curves, the opposed signed after-responses (OSARs) and the acceleration sensitivities. The fit obtained within the speed-tuning curves and the OSARs to motion offset observed in experiments are reported successfully as simulations, and the similar responses of the acceleration-sensitive neurons to step changes, step changes in step speed and step-wise modulation of stimulus speed are qualitatively consistent with physiological observations. Thus, a biologically plausible account for the response characteristics and the origin of the three properties are provided.

1 Introduction

Stabilizing images on the retina is very important for animal individuals to keep a clear vision. In vertebrate, both the vestibular system and the optokinetic system are involved in the generation of the compensatory eye movement caused by self-motion (for review, see Robinson and Fuchs 1995). In both, the vestibular system consists of two nuclei, the nucleus loquax and nucleus prepositus (LM) in primate and the nucleus of the horizontal optic tract (NHOT) of the macaque optic system (Omigawa 1984; Makiyama and Watanabe 1987). They are thought to be homologous to the pretectal nucleus of the optic tract (MOT) and the central nucleus of the accessory optic tract in mammals (Kallnick 1979; Makiyama and Watanabe 1987). Although a number of spatial and temporal similarities between the responses of vestibular neurons to self-motion and the responses of neurons in the optokinetic system to visual motion were reported (Miles 1984; Wiley et al. 1984; Fuchs 1988; Wiley and Cowder 2001; Robinson and Price 2001), whether visual neurons involved in optokinetic eye-egress would also respond to accelerations remained unknown for many years.

Recently, an experimental finding (Guo et al. 2004) in pigeons as LM revealed that about one-third of motion-sensitive neurons in the macular nucleus exhibit a response to acceleration of wide-field visual motion. The acceleration-sensitive responses show some novel responses properties, such as the phasically-shaped speed-tuning curves in the preferred direction and null-direction, an opponent inhibition during step changes in step speed and a non-monotonic velocity-tuning curve in the null direction. The acceleration-sensitive responses were observed in a simplified fact with its characteristics in detail (Robinson and Miles 1996; Wiley and Cowder 2000; Cowder and Wiley 2001) and were related to optokinetic eye-egress, for detail, see OSARs (Paxinos and Hobson 2002). And it is interesting to note that there exists an association between the shape of the speed-tuning curves and the presence of the after-response to target acceleration or deceleration, which also thought to be diagnostic for the presence or absence of response related to target acceleration or deceleration.

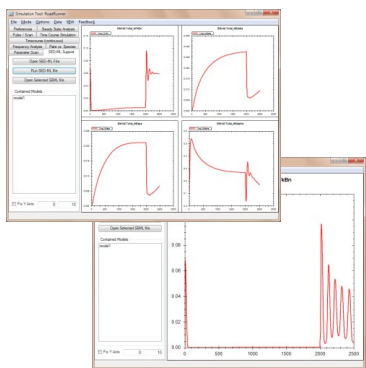

In this paper we propose a computational model to simulate the acceleration-sensitive neurons in pigeon optokinetic system. Based on the hypothesis that the slow adaptive depression plays a significant role in shaping responses of the acceleration-sensitive neurons to visual motion, a plausible explanation for the possible origin of the OSARs, the phasically-shaped speed-tuning curves and the acceleration sensitivities is presented.

SED-ED (Bioinformatics. 2012 Feb 25)

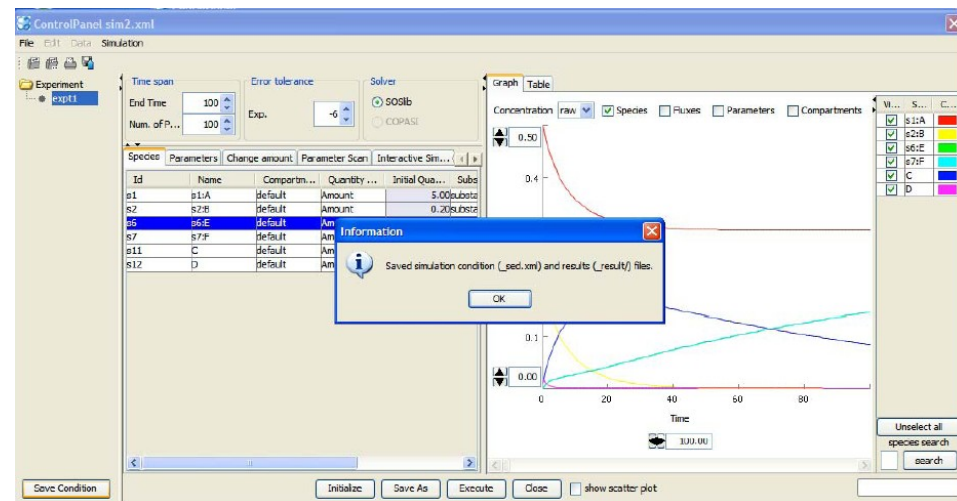

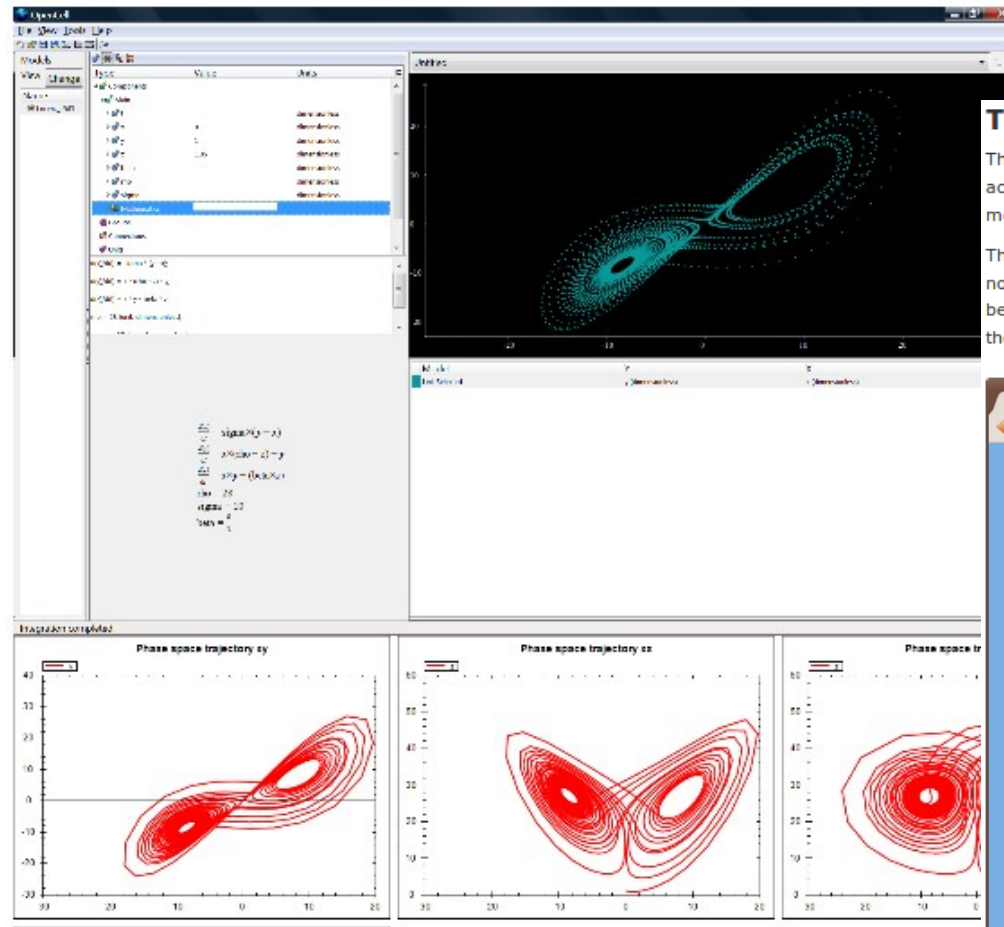

Fig.: SED-ML import/export in CellDesigner

http://sysbioapps.dyndns.org/SED-ML_Web_Tools

Example: SED-ML and the CellML repository

An OpenCell 0.8 session file is available. [SED-ML](#) can also be used to simulate this model, the simulation description is in [Lorenz_1963_sedml.xml](#), and the simulation experiment can be run using the [SED-ML Web Tools](#). The figures below show the results from OpenCell and from using [SED-ML](#).

The ORd human ventricular action potential model

This workspace houses a CellML 1.0 encoding of the 2011 O'Hara, Virág, Varró, & Rudy 2011 human ventricular action potential model (ORd). The original article is available at: <http://www.ncbi.nlm.nih.gov/pubmed> model was encoded based on the Matlab version of the code available from: <http://rudylab.wustl.edu>

The CellML 1.0 encoding of the ORd model was contributed by Steven Niederer. While the units in the not yet perfect, it is a match for the Matlab code and matches the simulation output for a single beat below shows the output of the simulation experiment [action-potential.xml](#) encoded in [SED-ML](#) using the model from Steve. This output is generated by running the simulation experiment using the [SED-ML](#)

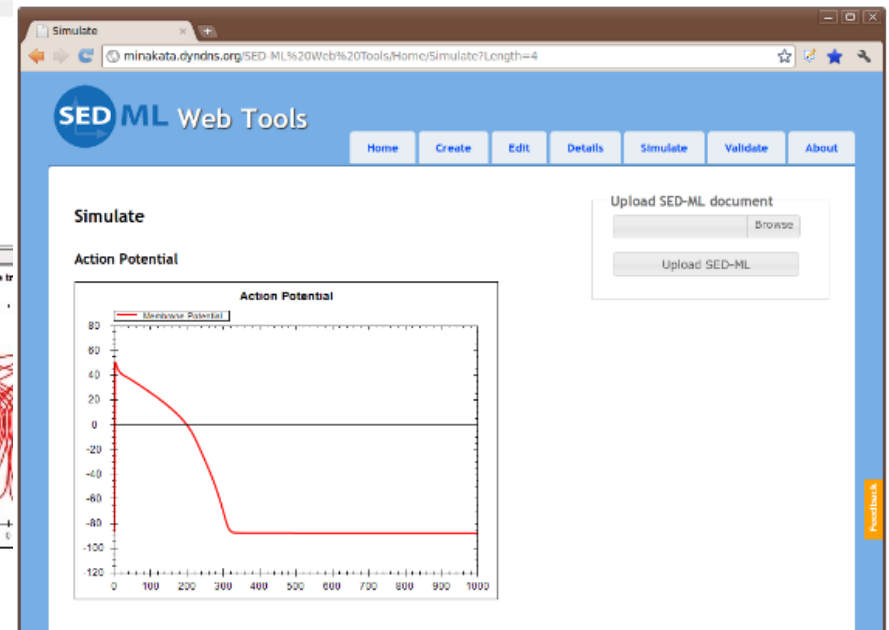

Fig.: CellML models with supplement SED-ML files. (CellML model repository)

Example: SED-ML for computational neuroscience

J Neurosci. 2002 Nov 1;22(21):9475-89.

Response of neurons in the lateral intraparietal area during a combined visual discrimination reaction time task.

Roitman JD, Shadlen MN.

Program in Neurobiology and Behavior, Department of Physiology and Biophysics, and Regional Primate Research Center, University of Washington, Seattle, Washington 98195-7290, USA.

1. Have a look at the current SED-ML L1 V1 Specification document on <http://sed-ml.org>
2. Try out some of the existing examples
<http://sed-ml.org>, <http://sourceforge.net/projects/libsedml>
3. Identify what is missing for you to encode your simulation experimental setups - What can you not express?
4. Submit a feature request & post it on the list
feature request tracker: <http://sourceforge.net/projects/sed-ml>
mailing list: sed-ml-discuss@lists.sourceforge.net
5. ... submit a proposal with example files and prototype
proposal tracker: <http://sourceforge.net/projects/sed-ml>

Thank you for your attention!

Frank Bergmann (editor, elected 2011-2014)
Frank T. Bergmann (PhD in Computational and Systems Biology) is a researcher at the [California Institute of Technology](#) where his primary interest is in standardization efforts around [SBML](#). He is also the lead developer of the [Systems Biology Workbench](#) along with the [LibSEDML library](#).

Dagmar Waltemath (editor, elected 2011-2014)
Dagmar Waltemath (Diploma degree in Computer Science) is guest researcher at the [Systems Biology and Bioinformatics group, Rostock](#). She works on the standardisation of simulation experiment descriptions in Computational Biology ([MIASE](#)).

Richard Adams (editor, elected 2011-2013)
Richard Adams (PhD in Cell Biology) is software project manager at the [Centre for Systems Biology, Edinburgh](#). He works on the [SBSI systems biology software framework](#), SED-ML tools and the jlibsedml Java library for SED-ML.

David Nickerson (editor, elected 2011-2013)
David Nickerson is a Research Fellow in the Auckland Bioengineering Institute where he leads the Auckland Kidney Physiome project. David is also involved in many aspects of the CellML project as well as various cardiac modeling projects. He also develops several CellML-related software tools.

Andrew Miller (editor, elected 2011-2012)
Andrew Miller is a researcher at the [Auckland Bioengineering Institute](#). His research interests focus around the representation of mathematical models; he is involved in the development of tools for processing [CellML](#) models, including SProS, a SED-ML processing service that forms part of the CellML API.

Nicolas Le Novère (editorial advisor)
[Nicolas Le Novère](#) is a group leader at the [EMBL-European Bioinformatics Institute](#). His research unfolds along two axis: 1) modelling neuronal signalling, at the molecular, sub-cellular and cellular levels, and 2) developing tools and resources for systems biology, in particular including standards.
